Euler Angles: Idea

- Represent object orientation as a sequence of rotations about X, Y, & Z,
 - e.g., roll (z) then pitch (x) then yaw (y).
- Or as a rotation matrix:

$$\begin{pmatrix} c_2c_3 & c_2s_3 & -s_2 & 0 \\ s_1s_2c_3 - c_1s_3 & s_1s_2s_3 + c_1c_3 & s_1c_2 & 0 \\ c_1s_2c_3 + s_1s_3 & c_1s_2s_3 - s_1c_3 & c_1c_2 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

- c_1 & s_1 are the x-axis cos & sin, etc.
-

Euler Angles: Good & Bad

- Easy for us to understand/specify
- Gimbal lock
 - Lose one DOF after some rotations
- How do we interpolate?

Global coordinate system

Local coordinate system attached to object

Angle & Axis Representation

- Going from one orientation to another can be represented as a single rotation about a single axis.

Quaternions

- A quaternion is a scalar and a vector
 - $q = [s, v]$
 - $[s, v] = [-s, -v]$
- Addition:
 - $[s_1, v_1] + [s_2, v_2] = [s_1 + s_2, v_1 + v_2]$
- Length:
 - $||q||$ of $[a, (b, c, d)] = \text{sqrt}(a^2, b^2, c^2, d^2)$
- Multiplication:
 - $q_1 * q_2 = [s_1 s_2 - v_1 \cdot v_2, s_1 v_2 + s_2 v_1 + v_1 \times v_2]$

Quaternions (cont.)

- A series of rotations can be concatenated by multiplying them together.
- Multiplicative identity:
 - $[1, (0, 0, 0)]$
- We can think of quaternions as being derived from Angle & Axis notation.
- Interpolation of quaternions is covered next week (Sec. 3.3)
