[Read Chapter 13] [Exercises 13.1, 13.2, 13.4]

- Control learning
- Control policies that choose optimal actions
- Q learning
- Convergence

# **Control Learning**

Consider learning to choose actions, e.g.,

- Robot learning to dock on battery charger
- Learning to choose actions to optimize factory output
- Learning to play Backgammon

Note several problem characteristics:

- Delayed reward
- Opportunity for active exploration
- Possibility that state only partially observable
- Possible need to learn multiple tasks with same sensors/effectors

## One Example: TD-Gammon

 $[\mathrm{Tesauro},\,1995]$ 

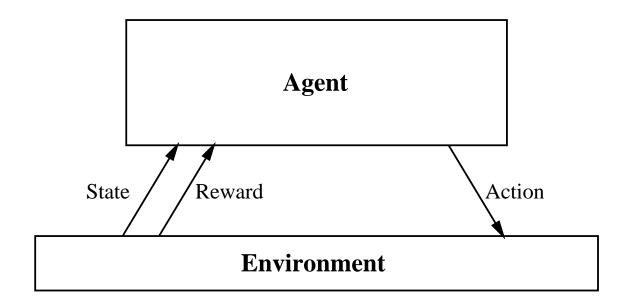

Learn to play Backgammon

Immediate reward

- +100 if win
- -100 if lose
- 0 for all other states

Trained by playing 1.5 million games against itself Now approximately equal to best human player

## Reinforcement Learning Problem

$$s_0 \xrightarrow{a_0} s_1 \xrightarrow{a_1} s_2 \xrightarrow{a_2} \dots$$

Goal: Learn to choose actions that maximize

$$r_0 + \gamma r_1 + \gamma^2 r_2 + \dots$$
, where  $0 \leq \gamma < 1$ 

lecture slides for textbook Machine Learning, T. Mitchell, McGraw Hill, 1997

## Markov Decision Processes

#### Assume

- $\bullet$  finite set of states S
- set of actions A
- at each discrete time agent observes state  $s_t \in S$ and chooses action  $a_t \in A$
- then receives immediate reward  $r_t$
- and state changes to  $s_{t+1}$
- Markov assumption:  $s_{t+1} = \delta(s_t, a_t)$  and  $r_t = r(s_t, a_t)$ 
  - -i.e.,  $r_t$  and  $s_{t+1}$  depend only on *current* state and action
  - functions  $\delta$  and r may be nondeterministic
  - functions  $\delta$  and r not necessarily known to agent

Execute actions in environment, observe results, and

• learn action policy  $\pi: S \to A$  that maximizes

$$E[r_t + \gamma r_{t+1} + \gamma^2 r_{t+2} + \ldots]$$

from any starting state in S

 $\bullet$  here  $0 \leq \gamma < 1$  is the discount factor for future rewards

Note something new:

- Target function is  $\pi: S \to A$
- but we have no training examples of form  $\langle s, a \rangle$
- training examples are of form  $\langle \langle s, a \rangle, r \rangle$

To begin, consider deterministic worlds...

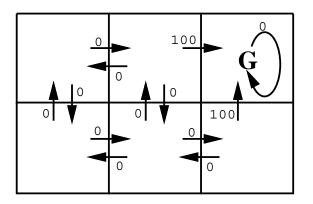

For each possible policy  $\pi$  the agent might adopt, we can define an evaluation function over states

$$V^{\pi}(s) \equiv r_t + \gamma r_{t+1} + \gamma^2 r_{t+2} + \dots$$
$$\equiv \sum_{i=0}^{\infty} \gamma^i r_{t+i}$$

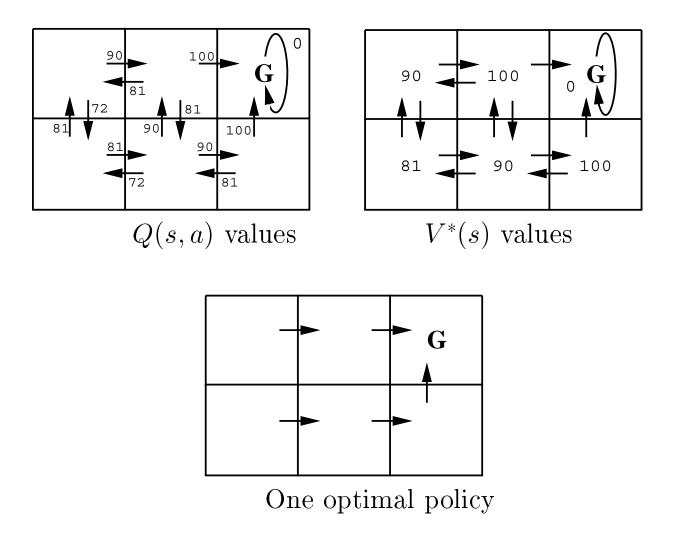

where  $r_t, r_{t+1}, \ldots$  are generated by following policy  $\pi$  starting at state s

Restated, the task is to learn the optimal policy  $\pi^*$ 

$$\pi^* \equiv \operatorname*{argmax}_{\pi} V^{\pi}(s), (\forall s)$$

r(s, a) (immediate reward) values

lecture slides for textbook Machine Learning, T. Mitchell, McGraw Hill, 1997

We might try to have agent learn the evaluation function  $V^{\pi^*}$  (which we write as  $V^*$ )

It could then do a look ahead search to choose best action from any state s because

$$\pi^*(s) = \operatorname*{argmax}_a[r(s,a) + \gamma V^*(\delta(s,a))]$$

A problem:

- This works well if agent knows  $\delta : S \times A \to S$ , and  $r : S \times A \to \Re$
- But when it doesn't, it can't choose actions this way

#### Q Function

Define new function very similar to  $V^*$ 

$$Q(s,a) \equiv r(s,a) + \gamma V^*(\delta(s,a))$$

If agent learns Q, it can choose optimal action even without knowing  $\delta$ !

$$\pi^*(s) = \operatorname*{argmax}_a[r(s,a) + \gamma V^*(\delta(s,a))]$$

$$\pi^*(s) = \operatorname*{argmax}_a Q(s, a)$$

 $\boldsymbol{Q}$  is the evaluation function the agent will learn

Note Q and  $V^*$  closely related:

$$V^*(s) = \max_{a'} Q(s, a')$$

Which allows us to write Q recursively as

$$Q(s_t, a_t) = r(s_t, a_t) + \gamma V^*(\delta(s_t, a_t))) = r(s_t, a_t) + \gamma \max_{a'} Q(s_{t+1}, a')$$

Nice! Let  $\hat{Q}$  denote learner's current approximation to Q. Consider training rule

$$\hat{Q}(s,a) \leftarrow r + \gamma \max_{a'} \hat{Q}(s',a')$$

where s' is the state resulting from applying action a in state s

## **Q** Learning for Deterministic Worlds

For each s, a initialize table entry  $\hat{Q}(s, a) \leftarrow 0$ 

Observe current state s

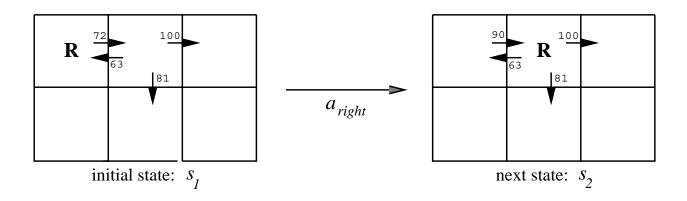

Do forever:

- Select an action a and execute it
- Receive immediate reward r
- Observe the new state s'
- Update the table entry for  $\hat{Q}(s, a)$  as follows:

$$\hat{Q}(s,a) \leftarrow r + \gamma \max_{a'} \hat{Q}(s',a')$$

•  $s \leftarrow s'$ 

# Updating $\hat{Q}$

$$\hat{Q}(s_1, a_{right}) \leftarrow r + \gamma \max_{a'} \hat{Q}(s_2, a') \\ \leftarrow 0 + 0.9 \max\{63, 81, 100\} \\ \leftarrow 90$$

notice if rewards non-negative, then

$$(\forall s, a, n) \quad \hat{Q}_{n+1}(s, a) \ge \hat{Q}_n(s, a)$$

and

$$(\forall s, a, n) \quad 0 \le \hat{Q}_n(s, a) \le Q(s, a)$$

 $\hat{Q}$  converges to Q. Consider case of deterministic world where see each  $\langle s, a \rangle$  visited infinitely often.

*Proof*: Define a full interval to be an interval during which each  $\langle s, a \rangle$  is visited. During each full interval the largest error in  $\hat{Q}$  table is reduced by factor of  $\gamma$ 

Let  $\hat{Q}_n$  be table after *n* updates, and  $\Delta_n$  be the maximum error in  $\hat{Q}_n$ ; that is

$$\Delta_n = \max_{s,a} |\hat{Q}_n(s,a) - Q(s,a)|$$

For any table entry  $\hat{Q}_n(s, a)$  updated on iteration n + 1, the error in the revised estimate  $\hat{Q}_{n+1}(s, a)$  is  $|\hat{Q}_{n+1}(s, a) - Q(s, a)| = |(r + \gamma \max_{a'} \hat{Q}_n(s', a')) - (r + \gamma \max_{a'} Q(s', a'))|$   $= \gamma |\max_{a'} \hat{Q}_n(s', a') - \max_{a'} Q(s', a')|$   $\leq \gamma \max_{a'} |\hat{Q}_n(s', a') - Q(s', a')|$   $\leq \gamma \max_{s'',a'} |\hat{Q}_n(s'', a') - Q(s'', a')|$  $|\hat{Q}_{n+1}(s, a) - Q(s, a)| \leq \gamma \Delta_n$  Note we used general fact that

 $|\max_{a} f_1(a) - \max_{a} f_2(a)| \le \max_{a} |f_1(a) - f_2(a)|$ 

#### Nondeterministic Case

What if reward and next state are non-deterministic?

We redefine V, Q by taking expected values

$$V^{\pi}(s) \equiv E[r_t + \gamma r_{t+1} + \gamma^2 r_{t+2} + \ldots]$$
$$\equiv E[\sum_{i=0}^{\infty} \gamma^i r_{t+i}]$$

$$Q(s,a) \equiv E[r(s,a) + \gamma V^*(\delta(s,a))]$$

#### Nondeterministic Case

Q learning generalizes to nondeterministic worlds Alter training rule to  $\hat{Q}_n(s,a) \leftarrow (1-\alpha_n)\hat{Q}_{n-1}(s,a) + \alpha_n[r + \max_{a'} \hat{Q}_{n-1}(s',a')]$ where

$$\alpha_n = \frac{1}{1 + visits_n(s, a)}$$

Can still prove convergence of  $\hat{Q}$  to Q [Watkins and Dayan, 1992]

## **Temporal Difference Learning**

Q learning: reduce discrepancy between successive Q estimates

One step time difference:

$$Q^{(1)}(s_t, a_t) \equiv r_t + \gamma \max_a \hat{Q}(s_{t+1}, a)$$

Why not two steps?

$$Q^{(2)}(s_t, a_t) \equiv r_t + \gamma r_{t+1} + \gamma^2 \max_a \hat{Q}(s_{t+2}, a)$$

Or n?

$$Q^{(n)}(s_t, a_t) \equiv r_t + \gamma r_{t+1} + \dots + \gamma^{(n-1)} r_{t+n-1} + \gamma^n \max_a \hat{Q}(s_{t+n}, a)$$

Blend all of these:

$$Q^{\lambda}(s_t, a_t) \equiv (1 - \lambda) \left[ Q^{(1)}(s_t, a_t) + \lambda Q^{(2)}(s_t, a_t) + \lambda^2 Q^{(3)}(s_t, a_t) \right]$$

 $Q^{\lambda}(s_t, a_t) \equiv (1-\lambda) \left[ Q^{(1)}(s_t, a_t) + \lambda Q^{(2)}(s_t, a_t) + \lambda^2 Q^{(3)}(s_t, a_t) + \lambda^2 Q^{$ 

$$Q^{\lambda}(s_t, a_t) = r_t + \gamma [ (1 - \lambda) \max_a \hat{Q}(s_t, a_t) \\ + \lambda \ Q^{\lambda}(s_{t+1}, a_{t+1}) ]$$

 $TD(\lambda)$  algorithm uses above training rule

- Sometimes converges faster than Q learning
- converges for learning  $V^*$  for any  $0 \le \lambda \le 1$ (Dayan, 1992)
- Tesauro's TD-Gammon uses this algorithm

## **Subtleties and Ongoing Research**

- Replace  $\hat{Q}$  table with neural net or other generalizer
- Handle case where state only partially observable
- Design optimal exploration strategies
- Extend to continuous action, state
- Learn and use  $\hat{\delta} : S \times A \to S$
- Relationship to dynamic programming
