

# Remember

- Midterm: Next Thursday (Feb 7)
- More on that next week

## Other Camera Controls

- The LookAt function is only for positioning camera
- Other ways to specify camera position/movement
  - Yaw, pitch, roll
  - Elevation, azimuth, twist
  - Direction angles

# Flexible Camera Control

- Sometimes, we want camera to move
- Like controlling a airplane's orientation
- Adopt aviation terms:
  - **Pitch:** nose up-down
  - **Roll:** roll body of plane
  - **Yaw:** move nose side to side

a) pitch

b) roll

c) yaw

# Yaw, Pitch and Roll Applied to Camera

- Similarly, yaw, pitch, roll with a camera

a) camera orientation

b) with roll

c) no roll

# Flexible Camera Control

- Create a camera class

```
class Camera
  private:
    Point3 eye;
    Vector3 u, v, n;... etc
```

- Camera functions to specify pitch, roll, yaw. E.g

```
cam.slide(-1, 0, -2); // slide camera forward -2 and left -1
cam.roll(30); // roll camera 30 degrees
cam.yaw(40); // yaw it 40 degrees
cam.pitch(20); // pitch it 20 degrees
```

# Recall: Final LookAt Matrix

- Slide along u, v or n
- Changes eye position
- Affects these components

$$\begin{bmatrix} ux & uy & uz & -\mathbf{e} \cdot \mathbf{u} \\ vx & vy & vz & -\mathbf{e} \cdot \mathbf{v} \\ nx & ny & nz & -\mathbf{e} \cdot \mathbf{n} \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

- Pitch, yaw, roll rotates u, v or n
- Changes changes these components

# Implementing Flexible Camera Control

- Camera class: maintains current (u,v,n) and eye position

```
class Camera
private:
    Point3 eye;
    Vector3 u, v, n;... etc
```

- User inputs desired roll, pitch, yaw angle or slide
  1. Roll, pitch, yaw: calculate modified vector (u', v', n')
  2. Slide: Calculate new eye position
  3. Update lookAt matrix, Load it into CTM

# Load Matrix into CTM

```
void Camera::setModelViewMatrix(void)
{ // load modelview matrix with camera values
  mat4 m;
  Vector3 eVec(eye.x, eye.y, eye.z); // eye as vector
  m[0] = u.x; m[4] = u.y; m[8] = u.z;  m[12] = -dot(eVec,u);
  m[1] = v.x; m[5] = v.y; m[9] = v.z;  m[13] = -dot(eVec,v);
  m[2] = n.x; m[6] = n.y; m[10] = n.z; m[14] = -dot(eVec,n);
  m[3] = 0;   m[7] = 0;   m[11] = 0;   m[15] = 1.0;
  CTM = m; // Finally, load matrix m into CTM Matrix
}
```

$$\begin{array}{ccc|c} ux & uy & uz & -e \cdot u \\ vx & vy & vz & -e \cdot v \\ nx & ny & nz & -e \cdot n \\ 0 & 0 & 0 & 1 \end{array}$$

- Call setModelViewMatrix after slide, roll, pitch or yaw
- Slide changes **eVec**,
- roll, pitch, yaw, change **u, v, n**

## Example: Camera Slide

- User changes eye by delU, delV or delN
- $\text{eye} = \text{eye} + \text{changes}(\text{delU}, \text{delV}, \text{delN})$
- Note: function below combines all slides into one

```
void camera::slide(float delU, float delV, float delN)
{
    eye.x += delU*u.x + delV*v.x + delN*n.x;
    eye.y += delU*u.y + delV*v.y + delN*n.y;
    eye.z += delU*u.z + delV*v.z + delN*n.z;
    setModelViewMatrix( );
}
```

E.g moving camera by  $D$  along its u axis  
=  $\text{eye} + Du$

## Example: Camera Roll

$$\mathbf{u}' = \cos(\alpha)\mathbf{u} + \sin(\alpha)\mathbf{v}$$

$$\mathbf{v}' = -\sin(\alpha)\mathbf{u} + \cos(\alpha)\mathbf{v}$$

```
void Camera::roll(float angle)
{ // roll the camera through angle degrees
  float cs = cos(3.142/180 * angle);
  float sn = sin(3.142/180 * angle);
  Vector3 t = u; // remember old u
  u.set(cs*t.x - sn*v.x, cs*t.y - sn*v.y, cs*t.z - sn*v.z);
  v.set(sn*t.x + cs*v.x, sn*t.y + cs*v.y, sn*t.z + cs*v.z)
  setModelViewMatrix( );
}
```

## Lecture 13: Projection (Part I)

---

Prof Emmanuel Agu

*Computer Science Dept.  
Worcester Polytechnic Institute (WPI)*

# Recall: 3D Viewing and View Volume

# Recall: Different View Volume Shapes

Orthogonal view volume  
(no foreshortening)

Perspective view volume  
(exhibits foreshortening)

- Different view volume => different look
- **Foreshortening?** Near objects bigger

# View Volume Parameters

- Need to set view volume parameters
  - **Projection type:** perspective, orthographic, etc.
  - Field of view and aspect ratio
  - Near and far clipping planes

# Field of View

- View volume parameter
- Determines how much of world in picture (vertically)
- Larger field of view = smaller objects drawn

# Near and Far Clipping Planes

- Only objects between near and far planes drawn

# Viewing Frustum

- Near plane + far plane + field of view = **Viewing Frustum**
- Objects outside the frustum are clipped

# Setting up View Volume/Projection Type

- Previous OpenGL projection commands **deprecated!!**
- Perspective view volume/projection:
  - `gluPerspective(fovy, aspect, near, far)` or
  - `glFrustum(left, right, bottom, top, near, far)`
- Orthographic:
  - `glOrtho(left, right, bottom, top, near, far)`
- Useful functions, so we implement similar in `mat.h`:
  - `Perspective(fovy, aspect, near, far)` or
  - `Frustum(left, right, bottom, top, near, far)`
  - `Ortho(left, right, bottom, top, near, far)`

What are these arguments? Next!

# Perspective(fovy, aspect, near, far)

- Aspect ratio used to calculate window width

## Frustum(left, right, bottom, top, near, far)

- Can use **Frustrum( )** in place of **Perspective()**
- Same view volume shape, different **arguments**

**near** and **far** measured from **camera**

# Ortho(left, right, bottom, top, near, far)

- For orthographic projection

**near** and **far** measured from **camera**

# Example Usage: Setting View Volume/Projection Type

```
void display()
{
    // clear screen
    glClear(GL_COLOR_BUFFER_BIT);
    .....
    // Set up camera position
    LookAt(0,0,1,0,0,0,0,1,0);

    .....
    // set up perspective transformation
    Perspective(fovy, aspect, near, far);

    .....
    // draw something
    display_all();    // your display routine
}
```

# Perspective Projection

- After setting view volume, then projection transformation
- Projection?
  - **Classic:** Converts 3D object to corresponding 2D on screen
  - How? Draw line from object to projection center
  - Calculate where each cuts projection plane

# Orthographic Projection

- How? Draw parallel lines from each object vertex
- The projection center is at infinite
- In short, use  $(x,y)$  coordinates, just drop  $z$  coordinates

# Demo

- Nate Robbins demo on projection

# Default View Volume/Projection?

- What if you user does not set up projection?
- Default OpenGL projection is orthogonal (Ortho( ));
- To project points within default view volume

# Homogeneous Coordinate Representation

default orthographic projection

$$\begin{aligned}x_p &= x \\y_p &= y \\z_p &= 0 \\w_p &= 1\end{aligned}$$

$$\mathbf{p}_p = \mathbf{M}\mathbf{p}$$

$$\mathbf{M} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

Default  
Projection  
Matrix

Vertices **before**  
Projection

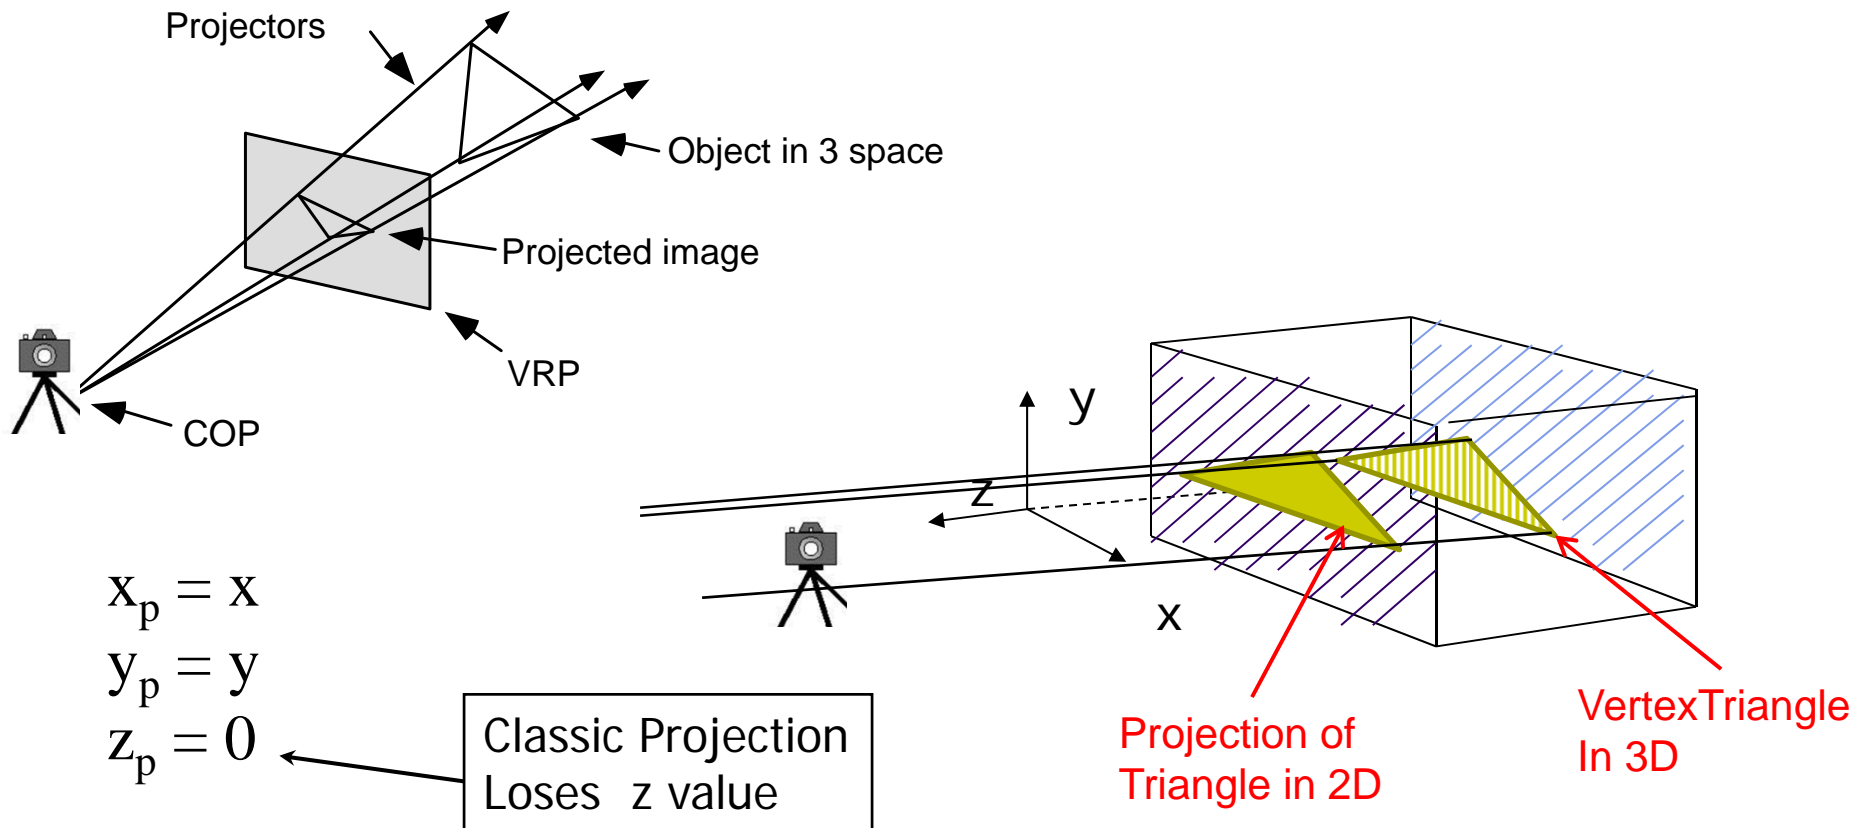

Vertices **after**  
Projection

In practice, can let  $\mathbf{M} = \mathbf{I}$ , set the z term to zero later

# The Problem with Classic Projection

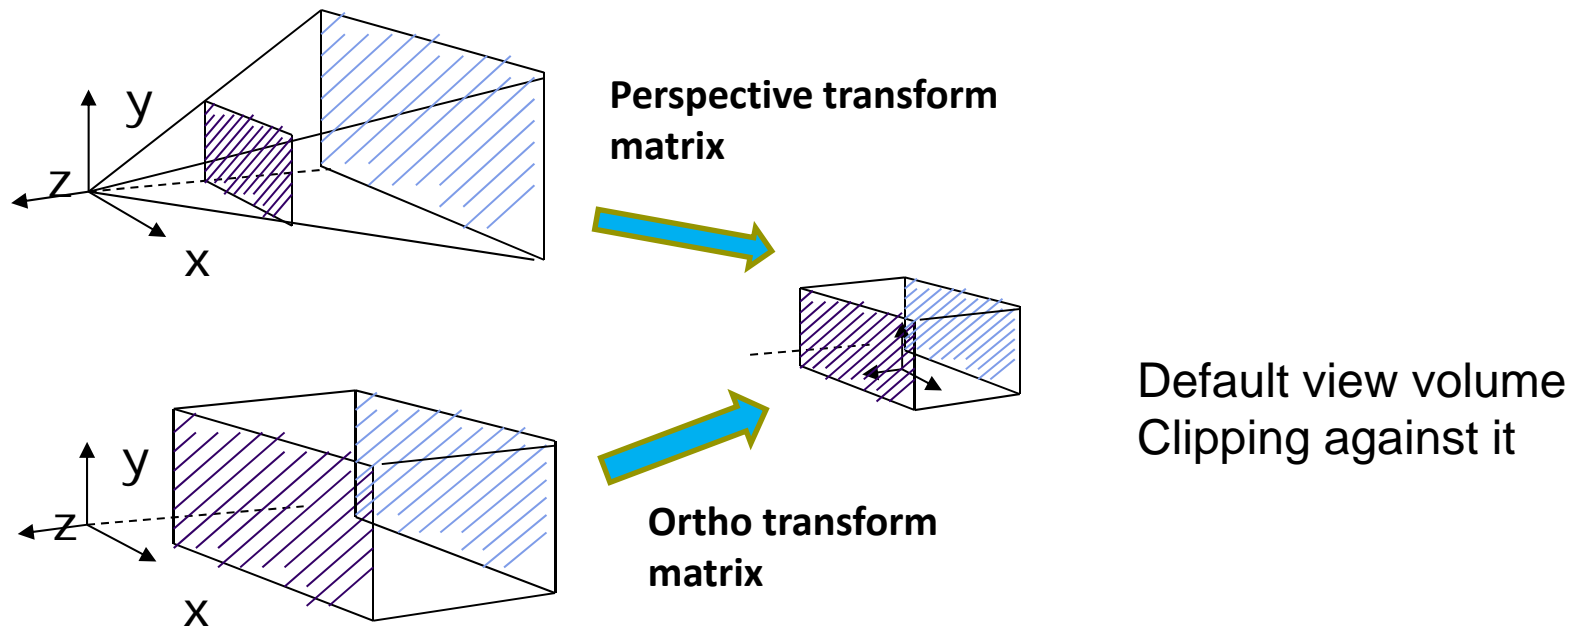

- Keeps (x,y) coordinates for drawing, drops z
- We may need z. Why?

# Normalization: Keeps z Value

- Most graphics systems use *view normalization*
- **Normalization:** convert all other projection types to orthogonal projections with the *default view volume*
