Computer Graphics (CS 543) Lecture 9: Shadows and Fog

Prof Emmanuel Agu

Computer Science Dept. Worcester Polytechnic Institute (WPI)

Introduction to Shadows

Shadows give information on relative positions of objects¹

Why shadows?More realism and atmosphere

Types of Shadow Algorithms

- Project shadows as separate objects (like Peter Pan's shadow)
 - Projective shadows
- As volumes of space that are dark
 - Shadow volumes [Franklin Crow 77]
- As places not seen from a light source looking at the scene
 - Shadow maps [Lance Williams 78]
- Fourth method used in ray tracing

Projective Shadows

- Oldest method: Used in early flight simulators
- Projection of polygon is polygon called shadow polygon

Projective Shadows

- Works for flat surfaces illuminated by point light
- For each face, project vertices V to find V' of shadow polygon
- Object shadow = union of projections of faces

Projective Shadow Algorithm

- Project light-object edges onto plane
- Algorithm:
 - First, draw ground plane/scene using specular+diffuse+ambient components
 - Then, draw shadow projections (face by face) using only ambient component

Projective Shadows for Polygon

- 1. If light is at (x_1, y_1, z_1)
- 2. Vertex at (x, y, z)
- Would like to calculate shadow polygon vertex V projected onto ground at (x_p, 0, z_p)

Projective Shadows for Polygon

- If we move original polygon so that light source is at origin
- Matrix *M* projects a vertex V to give its projection V' in shadow polygon

$$m = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & \frac{1}{-y_{l}} & 0 & 0 \\ & -y_{l} & & \end{bmatrix}$$

Building Shadow Projection Matrix

- 1. Translate source to origin with $T(-x_1, -y_1, -z_1)$
- 2. Perspective projection
- 3. Translate back by $T(x_i, y_i, z_i)$

$$M = \begin{bmatrix} 1 & 0 & 0 & x_l \\ 0 & 1 & 0 & y_l \\ 0 & 0 & 1 & z_l \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & -y_l & 0 & 0 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & -x_l \\ 0 & 1 & 0 & -y_l \\ 0 & 0 & 1 & -z_l \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

Final matrix that projects Vertex V onto V' in shadow polygon

Code snippets?

Set up projection matrix in OpenGL application

float light[3]; // location of light
mat4 m; // shadow projection matrix initially identity

```
M[3][1] = -1.0/light[1];
M = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & \frac{1}{-y_{1}} & 0 & 0 \\ -y_{1} & 0 & 0 \end{bmatrix}
```

Projective Shadow Code

• Set up object (e.g a square) to be drawn

```
point4 square[4] = {vec4(-0.5, 0.5, -0.5, 1.0}
{vec4(-0.5, 0.5, -0.5, 1.0}
{vec4(-0.5, 0.5, -0.5, 1.0}
{vec4(-0.5, 0.5, -0.5, 1.0}
```

- Copy square to VBO
- Pass modelview, projection matrices to vertex shader

What next?

- Next, we load model_view as usual then draw original polygon
- Then load shadow projection matrix, change color to black, re-render polygon

Shadow projection Display() Function

```
void display()
{
    mat4 mm;
    // clear the window
    glClear(GL_COLOR_BUFFER_BIT | GL_DEPTH_BUFFER_BIT);
    // render red square (original square) using modelview
    // matrix as usual (previously set up)
    glUniform4fv(color_loc, 1, red);
    glDrawArrays(GL_TRIANGLE_STRIP, 0, 4);
```

Shadow projection Display() Function

```
11
    modify modelview matrix to project square
// and send modified model view matrix to shader
mm = model view
        * Translate(light[0], light[1], light[2]
        *m
        * Translate(-light[0], -light[1], -light[2]);
glUniformMatrix4fv(matrix loc, 1, GL TRUE, mm);
//and re-render square as
// black square (or using only ambient component)
 glUniform4fv(color loc, 1, black);
 glDrawArrays (GL TRIANGLE STRIP, 0, 4);
 glutSwapBuffers();
                                                        M = \begin{bmatrix} 1 & 0 & 0 & x_l \\ 0 & 1 & 0 & y_l \\ 0 & 0 & 1 & z_l \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & \frac{1}{-\mathcal{V}_l} & 0 & 0 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & -x_l \\ 0 & 1 & 0 & -y_l \\ 0 & 0 & 1 & -z_l \\ 0 & 0 & 0 & 1 \end{bmatrix}
```

Fog

Fog example

- Fog is atmospheric effect
 - Better realism, helps determine distances

Fog

- Fog was part of OpenGL fixed function pipeline
- Programming fixed function fog
 - Parameters: Choose fog color, fog model
 - Enable: Turn it on
- Fixed function fog deprecated!!
- Shaders can implement even better fog
- Shaders implementation: fog applied in fragment shader just before display

Rendering Fog

• Mix some color of fog: \mathbf{c}_f + color of surface: \mathbf{c}_s

$$\mathbf{c}_p = f\mathbf{c}_f + (1 - f)\mathbf{c}_s \qquad f \in [0, 1]$$

- If *f* = 0.25, output color = 25% fog + 75% surface color
 - f computed as function of distance z
 - 3 ways: linear, exponential, exponential-squared
 - Linear:

$$f = \frac{z_{end} - z_p}{z_{end} - z_{start}}$$

Fog Shader Fragment Shader Example $f = \frac{z_{end} - z_p}{z_{end} - z_{star}}$ float dist = abs(Position.z); Float fogFactor = (Fog.maxDist - dist)/ Fog.maxDist - Fog.minDist); fogFactor = clamp(fogFactor, 0.0, 1.0);vec3 shadeColor = ambient + diffuse + specular vec3 color = mix(Fog.color, shadeColor,fogFactor);

```
FragColor = vec4(color, 1.0);
```

$$\mathbf{c}_p = f\mathbf{c}_f + (1 - f)\mathbf{c}_s$$

Fog

- Exponential $f = e^{-d_f z_p}$
- Squared exponential $f = e^{-(d_f z_p)^2}$
- Exponential derived from Beer's law
 - **Beer's law:** intensity of outgoing light diminishes exponentially with distance, similar to real life

Fog Optimizations

- f values for different depths (z_P)can be pre-computed and stored in a table on GPU
- Distances used in *f* calculations are planar
- Can also use Euclidean distance from viewer or radial distance to create radial fog
