Fourier Transform

- Main idea: Any periodic function can be decomposed into a summation of sines and cosines

$$f(x) = \sin x + \frac{1}{3} \sin 2x + \frac{1}{5} \sin 4x$$
Fourier Transform: Why?

- Mathematically easier to analyze effects of transmission medium, noise, etc on simple sine functions, then add to get effect on complex signal

\[ f(x) = \sin x + \frac{1}{3} \sin 2x + \frac{1}{5} \sin 4x \]
Fourier Transform: Some Observations

Observation 1: The sines have different frequencies (not same)

Observation 2: Frequencies of sines are multiples of each other (called harmonics)
- Frequency = 1x
- Frequency = 2x
- Frequency = 4x

Observation 3: Different amounts of different sines added together (e.g. 1/3, 1/5, etc)

\[ f(x) = \sin x + \frac{1}{3} \sin 2x + \frac{1}{5} \sin 4x \]
Fourier Transform: Another Example

Square wave

Approximation Using sines

\[ f(x) = \sin x + \frac{1}{3} \sin 3x + \frac{1}{5} \sin 5x + \frac{1}{7} \sin 7x \]

Observation 4: The sine terms go to infinity. The more sines we add, the closer the approximation of the original.
Who is Fourier?

- French mathematician and physicist
- Lived 1768 - 1830
Fourier Series Expansion

- If $f(x)$ is **periodic function** of period $2T$
- **Fourier series expansion**

$$f(x) = a_0 + \sum_{n=1}^{\infty}(a_n \cos \frac{n\pi x}{T} + b_n \sin \frac{n\pi x}{T})$$

Where

$$a_0 = \frac{1}{T} \int_{-T}^{T} f(x) dx$$

$$a_n = \frac{1}{T} \int_{-T}^{T} f(x) \cos \frac{n\pi x}{T} dx, \ n = 1,2,3,...$$

$$b_n = \frac{1}{T} \int_{-T}^{T} f(x) \sin \frac{n\pi x}{T} dx, \ n = 1,2,3,...$$

- $a_n$ and $b_n$ called **Fourier coefficients**
Complex Form of Fourier Series Expansion

- Fourier series expansion of $f(x)$

$$f(x) = a_0 + \sum_{n=1}^{\infty} (a_n \cos \frac{n\pi x}{T} + b_n \sin \frac{n\pi x}{T})$$

can be expressed in complex form as:

$$f(x) = \sum_{n=-\infty}^{\infty} c_n \exp(\cos \frac{in\pi x}{T})dx$$

where

$$c_n(x) = \frac{1}{2T} \int_{-T}^{T} f(x) \exp(\frac{-in\pi x}{T})dx$$
Fourier Series of Periodic Functions

- (Almost) any periodic function $g(x)$ with fundamental frequency $\omega_0$ can be described as a sum of sinusoids

\[ g(x) = \sum_{k=0}^{\infty} [A_k \cos(k\omega_0 x) + B_k \sin(k\omega_0 x)] \]

- This infinite sum is called a **Fourier Series**
- Summed sines and cosines are multiples of the fundamental frequency (harmonics)
- $A_k$ and $B_k$ called **Fourier coefficients**
  - Not known initially but derived from original function $g(x)$ during Fourier analysis
Fourier Integral

- For non-periodic functions we can get similar results by letting period $T \to \infty$ similar ideas yield Fourier Integral (integration of densely packed sines and cosines)

\[ g(x) = \int_0^\infty A_\omega \cos(\omega x) + B_\omega \sin(\omega x) \, d\omega \]

where coefficients can be found as

\[ A_\omega = A(\omega) = \frac{1}{\pi} \int_{-\infty}^{\infty} g(x) \cdot \cos(\omega x) \, dx \]

\[ B_\omega = B(\omega) = \frac{1}{\pi} \int_{-\infty}^{\infty} g(x) \cdot \sin(\omega x) \, dx \]
Fourier Transform

- **Fourier Transform:** Transition of function $g(x)$ to its Fourier spectrum $G(\omega)$

\[
G(\omega) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} g(x) \cdot \left[ \cos(\omega x) - i \cdot \sin(\omega x) \right] \, dx \\
= \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} g(x) \cdot e^{-i\omega x} \, dx.
\]

- **Inverse Fourier Transform:** Reconstruction of original function $g(x)$ from its Fourier spectrum $G(\omega)$

\[
g(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} G(\omega) \cdot \left[ \cos(\omega x) + i \cdot \sin(\omega x) \right] \, d\omega \\
= \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} G(\omega) \cdot e^{i\omega x} \, d\omega.
\]

- $G(\omega) + g(\omega)$ called **Fourier transform pair**
1D Discrete Fourier Transform

- Image is a discrete 2D function!!
- For discrete functions we need only finite number of functions
- For example, consider the discrete sequence
  \[ 1, 1, 1, 1, -1, -1, -1, -1 \]
  - Above is discrete approximation to square wave
  - Can use Fourier transform to express as sum of 2 sine functions
Definition of 1D DFT

- Suppose

\[ f = [f_0, f_1, f_2, \ldots, f_{N-1}] \]

is a sequence of length \( N \)

\[ F = [F_0, F_1, F_2, \ldots, F_{N-1}] \]

where

\[ F_u = \frac{1}{N} \sum_{x=0}^{N-1} \exp \left[ -2\pi i \frac{xu}{N} \right] f_x \]

- **Interpretation:** Basis functions completes \( x \) cycles over distance \( N \)
- Similar to Fourier series expansion
- Instead of integral, we now have a finite sum

Compare with complex form of coefficients

\[ c_n(x) = \frac{1}{2T} \int_{-T}^{T} f(x) \exp \left( -\frac{inx}{T} \right) dx \]
Inverse 1D DFT

- Formula for inverse

\[ x_u = \sum_{x=0}^{N-1} \exp \left[ 2\pi i \frac{ux}{N} \right] F_u \]

- Compared to DFT equation,
  - The inverse has no scaling factor \(1/N\)
  - The sign inside the square bracket has been changed to +ve
Fast Fourier Transform (FFT)

- Many ways to compute DFT quickly
- Fast Fourier Transform (FFT) algorithm is one such way
- One FFT computation method
  - Divides original vector into 2
  - Calculates FFT of each half recursively
  - Merges results
FFT Computation Time Savings

- **Direct computation takes time:** $2^{2n}$ multiplications
- **FFT method takes:** $n2^n$ multiplications
- **Time savings:** $2^n/n$

2D DFT

• Thus if the matrix $F$ is the Fourier Transform of $f$ we can write

$$F = \mathcal{F}(f)$$

• The original matrix $f$ is the Inverse Fourier Transform of $F$

$$f = \mathcal{F}^{-1}(F).$$

• We have seen that a 1D function can be written as a sum of sines and cosines

• Image can be thought of as 2D function $f$ that can be expressed as a sum of a sines and cosines along 2 dimensions
2D Fourier Transform

- Can be expressed as weighted sum of sines and cosines

\[ e^{i2\pi \left( \frac{mu}{M} + \frac{nv}{N} \right)} = e^{i(\omega_m u + \omega_n v)} \]

\[ = \cos \left[ 2\pi \left( \frac{mu}{M} + \frac{nv}{N} \right) \right] + i \sin \left[ 2\pi \left( \frac{mu}{M} + \frac{nv}{N} \right) \right] \]

\[ \mathcal{C}_{M,N}^{m,n}(u,v) \]

\[ \mathcal{S}_{M,N}^{m,n}(u,v) \]

- \( m \) specifies how many cycles basis function performs over distance of \( M \) units

- \( n \) specifies how many cycles basis function performs over distance of \( N \) units
2D Fourier Transform

- For $M \times N$ matrix, forward and inverse fourier transforms can be written

$$F(u, v) = \sum_{x=0}^{M-1} \sum_{y=0}^{N-1} f(x, y) \exp \left[ -2\pi i \left( \frac{xu}{M} + \frac{yv}{N} \right) \right].$$

$$f(x, y) = \frac{1}{MN} \sum_{u=0}^{M-1} \sum_{v=0}^{N-1} F(u, v) \exp \left[ 2\pi i \left( \frac{xu}{M} + \frac{yv}{N} \right) \right].$$

where
- $x$ indices go from $0... M - 1$ ($x$ cycles over distance $M$)
- $y$ indices go from $0... N - 1$ ($y$ cycles over distance $N$)
2D Cosines functions

Orientation depend on $m$ and $n$
2D Fourier Transform: Corrugation of Functions

- Previous image just summed cosines
- Essentially, 2D Fourier Transform rewrites the original matrix by **summing sines and cosines in 2 direction = corrugations**

Corrugations result when sines and cosines are summed in 2 directions
Properties of 2D Fourier Transform

- All properties of 1D Fourier transform apply + additional properties
- **Similarity:** Forward and inverse transforms are similar except
  1. scale factor $1/MN$ in inverse transform
  2. Negative sign in exponent of forward transform

\[
F(u, v) = \sum_{x=0}^{M-1} \sum_{y=0}^{N-1} f(x, y) \exp \left[ -2\pi i \left( \frac{xu}{M} + \frac{yu}{N} \right) \right].
\]

\[
f(x, y) = \frac{1}{MN} \sum_{u=0}^{M-1} \sum_{v=0}^{N-1} F(u, v) \exp \left[ 2\pi i \left( \frac{xu}{M} + \frac{yu}{N} \right) \right].
\]
Properties of 2D Fourier Transform

\[ F(u, v) = \sum_{x=0}^{M-1} \sum_{y=0}^{N-1} f(x, y) \exp \left[ -2\pi i \left( \frac{xu}{M} + \frac{yu}{N} \right) \right]. \]

\[ f(x, y) = \frac{1}{MN} \sum_{u=0}^{M-1} \sum_{v=0}^{N-1} F(u, v) \exp \left[ 2\pi i \left( \frac{xu}{M} + \frac{yu}{N} \right) \right]. \]

- **DFT as spatial filter:** These values are just basis functions (are independent of \( f \) and \( F \))

\[ \exp \left[ \pm 2\pi i \left( \frac{xu}{M} + \frac{yu}{N} \right) \right] \]

- Can be computed in advance, put into formulas later
- Implies each value \( F(u, v) \) obtained by multiplying every value of \( f(x, y) \) by a fixed value, then adding up all results (similar to a filter!)
- **DFT can be considered a linear spatial filter as big as the image**
Separability

- Notice that Fourier transform “filter elements” can be expressed as products

\[
\exp \left[ 2\pi i \left( \frac{xu}{M} + \frac{yv}{N} \right) \right] = \exp \left[ 2\pi i \frac{xu}{M} \right] \exp \left[ 2\pi i \frac{yv}{N} \right]
\]

2D DFT \hspace{1cm} 1D DFT (row) \hspace{1cm} 1D DFT (column)

- Formula above can be broken down into simpler formulas for 1D DFT

\[
F(u) = \sum_{x=0}^{M-1} f(x) \exp \left[ -2\pi i \frac{xu}{M} \right],
\]

\[
f(x) = \frac{1}{M} \sum_{u=0}^{M-1} F(u) \exp \left[ 2\pi i \frac{xu}{M} \right]
\]
Properties: Separability of 2D DFT

- Using their separability property, can use 1D DFTs to calculate rows then columns of 2D Fourier Transform

(a) Original image  (b) DFT of each row of (a)  (c) DFT of each column of (b)
## Implementation of 2D DFT

- Can use separability to implement 2D DFT as sequence of 1D DFTs on rows and columns

```plaintext
1: `SEPARABLE 2D-DFT (g)` \( \triangleright g(u, v) \in \mathbb{C}, 0 \leq u < M, 0 \leq v < N \)
2: `for v ← 0 \ldots N-1` do
3:     Let \( g(\cdot, v) \) be the \( v \)th row vector of \( g \):
4:     Replace \( g(\cdot, v) \) by \( \text{DFT}(g(\cdot, v)) \)
5: `for u ← 0 \ldots M-1` do
6:     Let \( g(u, \cdot) \) be the \( u \)th column vector of \( g \):
7:     Replace \( g(u, \cdot) \) by \( \text{DFT}(g(u, \cdot)) \)

`Remark:` \( g(u, v) \equiv G(u, v) \in \mathbb{C} \) now contains the discrete 2D spectrum.
8: `return g`
```
Properties of 2D DFT

- **Linearity**: DFT of a sum is equal to sum (or multiplication) of the individual DFT's
  
  \[ \mathcal{F}(f + g) = \mathcal{F}(f) + \mathcal{F}(g) \]
  \[ \mathcal{F}(kf) = k\mathcal{F}(f) \quad k \text{ is a scalar} \]

- Useful property for dealing with degradations that can be expressed as a sum (e.g. noise)
  \[ d = f + n \]
  Where \( f \) is original image, \( n \) is the noise, \( d \) is degraded image

- We can find fourier transform as:
  \[ \mathcal{F}(d) = \mathcal{F}(f) + \mathcal{F}(n) \]

- Noise can be removed/reduced by modifying transform of \( n \)
Convolution using DFT

- DFT provides alternate method to do convolution of image $M$ with spatial filter $S$
  1. Pad $S$ to make it same size as $M$, yielding $S'$
  2. Form DFTs of both $M$ and $S'$
  3. Multiply $M$ and $S'$ element by element

\[ \mathcal{F}(M) \cdot \mathcal{F}(S') \]

1. Take inverse transform of result

\[ \mathcal{F}^{-1}(\mathcal{F}(M) \cdot \mathcal{F}(S')) \]

- Essentially

\[ M \ast S = \mathcal{F}^{-1}(\mathcal{F}(M) \cdot \mathcal{F}(S')) \]

Or equivalently the convolution $M \ast S$

\[ \mathcal{F}(M \ast S) = \mathcal{F}(M) \cdot \mathcal{F}(S') \]
Convolution using DFT

- Large speedups if $S$ is large
- Example: $M = 512 \times 512$, $S = 32 \times 32$
- Direct computation:
  - $32^2 = 1024$ multiplications for each pixel
  - Total multiplications for entire image $= 512 \times 512 \times 1024 = 268,435,456$ multiplications
- Using DFT:
  - Each row requires 4608 multiplications
  - Multiplications for rows $= 4608 \times 512 = 2,359,296$ multiplications
  - Repeat for columns, DFT of image $= 4718592$ multiplications
  - Need same for DFT of filter and for inverse DFT.
  - Also need $512 \times 512$ multiplications for product of 2 transforms
  - Total multiplications $= 4718592 \times 3 + 262144 = 14,417,920$
DC Component

- Recall that:

\[
F(u, v) = \sum_{x=0}^{M-1} \sum_{y=0}^{N-1} f(x, y) \exp \left[ -2\pi i \left( \frac{xu}{M} + \frac{yu}{N} \right) \right]
\]

- The value \( F(0,0) \) of the DFT is called the dc coefficient

- If we put \( u = v = 0 \), then

\[
F(0,0) = \sum_{x=0}^{M-1} \sum_{y=0}^{N-1} f(x, y) \exp(0) = \sum_{x=0}^{M-1} \sum_{y=0}^{N-1} f(x, y)
\]

- Essentially \( F(0,0) \) is the sum of all terms in the original matrix
Centering DFT Spectrum

- $F(0,0)$ at top left corner
- For display, convenient to have DC component in center
- Just swap four quadrants of Fourier transform

Swap 4 quadrants to center DC component

DFT spectrum after centering
Centering DFT Spectrum

(a) Original Image
(b) Non-centered spectrum
(c) Centered spectrum
Conjugate Symmetry

- DFT shows conjugate symmetry
- Half of the transform is mirror image of conjugate of other half
- **Implication:** information is contained in only half of a transform
- Other half is redundant
Conjugate Symmetry

Thus, if we put $u = -u$, and $v = -v$ into the DFT equation

$$F(u, v) = \sum_{x=0}^{M-1} \sum_{y=0}^{N-1} f(x, y) \exp \left[-2\pi i \left(\frac{xu}{M} + \frac{yu}{N}\right)\right]$$

Then

$$\mathcal{F}(u, v) = \mathcal{F}^*(-u + pM, -v + qN)$$

for any integers $p$ and $q$
Displaying Transforms

- As elements are complex numbers, we can view magnitudes \( |F(u, v)| \) directly.
- Displaying magnitudes of Fourier transforms called spectrum of the transform.

- **Problem:** DC component much larger than other values.
  - Displays white dot in middle surrounded by black.
- So stretch transform values by displaying log of transform

\[
\log(1 + |F(u, v)|)
\]
Examples of DFTs

- Suppose we have as input a constant image of all 1’s, $f(x,y) = 1$
- The DFT yields just a DC component, 0 everywhere else
- In this example, DC component is sum of all elements = 64
DFT of Image

- Consider DFT of image with single edge
- For display, DC component shifted to center
- Log of magnitudes of Fourier Transform displayed
DFT Example: A Box

Box

DFT
DFT Example: Rotated Box

Rotated Box

DFT
DFT Example: A Circle

- **Note:** Ringing caused by sharp cutoff of circle
- Ringing does not occur if circle cutoff is gentle
DFT Computation: Repeated Image

- DFT computation assumes image repeated horizontally and vertically
- Large intensity transition at edges = vertical and horizontal line in middle of spectrum after shifting
- Effects of sharp transitions affects many pixels
Windowing

- Can multiply image by windowing function $w(u,v)$ before DFT to reduce sharp transitions between ends of repeated images.
- Ideally, causes image to drop off towards ends, reducing transitions.
Some Proposed Windowing Functions

</tbody>
</table>
Some Proposed Windowing Functions
Some Proposed Windowing Functions
Application of Windowing Functions
Filtering in Frequency Domain

- one reason for using Fourier transform in image processing is due to convolution theorem
- Spatial convolution can be performed by element-wise multiplication of the Fourier transform by suitable “filter matrix”
Ideal Low Pass Filtering

- **Low pass filter:** Keep frequencies **below** a certain frequency
- Low pass filtering causes **blurring**
- After DFT, DC components and low frequency components are towards center
- May specify frequency cutoff as circle c
Ideal Low Pass Filtering

- Multiply Image Fourier Transform $F$ by some filter matrix $m$

$$m(x, y) = \begin{cases} 
1 & \text{if } (x, y) \text{ is closer to the center than some value } D, \\
0 & \text{if } (x, y) \text{ is further from the center than } D.
\end{cases}$$
Ideal Low Pass Filtering

- Low pass filtered image is inverse Fourier Transform of product of $F$ and $m$
  \[ \mathcal{F}^{-1}(F \cdot m) \]

- Example: Consider the following image and its DFT
Ideal Low Pass Filtering

Applying low pass filter to DFT
Cutoff D = 15

Image after inversion

low pass filter
Cutoff D = 5

Note: Sharp filter Cutoff causes ringing

low pass filter
Cutoff D = 30
Ideal High Pass Filtering

- Opposite of low pass filtering: eliminate center (low frequency values), keeping others
- High pass filtering causes image **sharpening**
- If we use circle as cutoff again, size affects results
  - Large cutoff = More information removed
Ideal High Pass Filtering: Effect of Cutoffs

High pass filtering of DFT with filter
Cutoff $D = 5$

Low cutoff frequency removes only few lowest frequencies

High pass filtering of DFT with filter
Cutoff $D = 30$

High cutoff frequency removes many frequencies, leaving only edges
Highpass Filtering Example

Butterworth Filtering

- Sharp cutoff leads to ringing
- To avoid ringing, can use circle with more gentle cutoff slope
- **Butterworth filters** have more gentle cutoff slopes
- Ideal low pass filter
  \[ f(x) = \begin{cases} 
  1 & \text{if } x < D \\
  0 & \text{if } x \geq D 
  \end{cases} \]

- Butterworth
  - low pass filter
  \[ f(x) = \frac{1}{1 + (x/D)^{2n}} \]

- \( n \) called **order** of the filter, controls sharpness of cutoff
Butterworth High Pass Filtering

- Ideal high pass filter

\[ f(x) = \begin{cases} 
1 & \text{if } x > D \\
0 & \text{if } x \leq D 
\end{cases} \]

- Butterworth high pass filter

\[ f(x) = \frac{1}{1 + (D/x)^{2n}} \]
Low Pass Butterworth Filtering

- Low pass filtering removes high frequencies, blurs image
- Gentler cutoff eliminates ringing artifact

DFT of Image after low pass Butterworth filtering

Resulting image after inverse DFT
High Pass Butterworth Filtering

DFT of Image after high pass Butterworth filtering

Resulting image after inverse DFT
Gaussian Filtering

- Gaussian filters can be applied in frequency domain
- Same steps
  - Create gaussian filter
  - Multiply (DFT of image) by (gaussian filter)
  - Invert result
- **Note:** Fourier transform of gaussian is also a gaussian,
- Just apply gaussian multiply directly (no need to find Fourier transform)
Frequency Domain Low Pass Gaussian Filtering

(a) $\sigma = 10$

(b) Resulting image

(c) $\sigma = 30$

(d) Resulting image
Lowpass Filtering Examples

A low pass Gaussian filter can be used to connect broken text

Historically, certain computer programs were written using only two digits rather than four to define the applicable year. Accordingly, the company's software may recognize a date using "00" as 1900 rather than the year 2000.

Lowpass Filtering Examples

Different lowpass Gaussian filters used to remove blemishes in a photograph

Frequency Domain High Pass Gaussian Filtering

(a) Using $\sigma = 10$

(b) Using $\sigma = 30$
Frequency Domain
Removal of Periodic Noise

- Recall: periodic noise could not be removed in spatial domain
- Periodic noise can be removed in frequency domain
- Periodic noise shows up as spikes away from origin in DFT
- Higher frequency noise = further away from origin
Frequency Domain
Removal of Periodic Noise

- 2 ways to remove periodic noise in frequency domain
  - Notch Filter
  - Band reject filter
- Notch filter: Set rows, columns of DFT corresponding to noise = 0
- Removes much of the periodic noise

![Notch Filter](image1)

Result after notch filter applied then inverted
Frequency Domain Removal of Periodic Noise: Band Reject Filter

- Create filter with 0's at radius of noise from center, 1 elsewhere
- Apply filter to DFT
2D Fourier Transform Examples: Scaling

- Stretching image => Spectrum contracts
- And vice versa
2D Fourier Transform Examples: Periodic Patterns

- Repetitive periodic patterns appear as distinct peaks at corresponding positions in spectrum.
2D Fourier Transform Examples: Rotation

- Rotating image => Rotates spectra by same angle/amount
2D Fourier Transform Examples: Oriented, elongated Structures

- Man-made elongated regular patterns in image => appear dominant in spectrum
2D Fourier Transform Examples: Natural Images

- Repetitions in natural scenes => less dominant than man-made ones, less obvious in spectra
2D Fourier Transform Examples: Natural Images

- Natural scenes with repetitive patterns but no dominant orientation => do not stand out in spectra
2D Fourier Transform Examples: Printed Patterns

- Regular diagonal patterns caused by printing => Clearly visible/removable in frequency spectrum.
