

Elementary TCP Sockets

Chapter 4

UNIX Network Programming

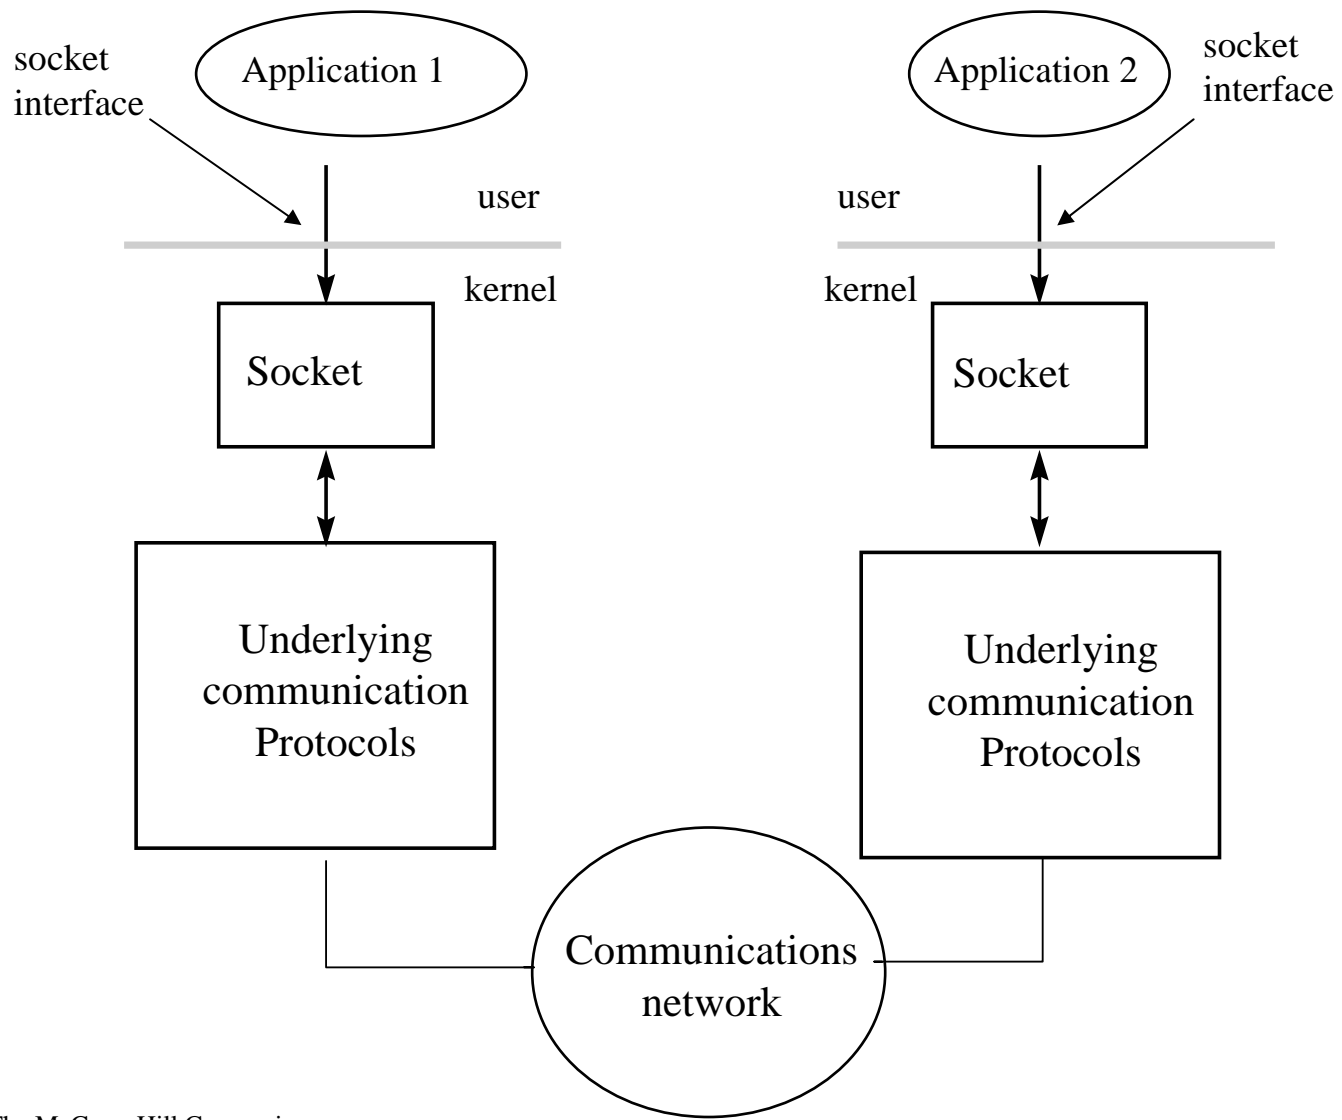

Vol. 1, Second Ed. Stevens

IPv4 Socket Address Structure

*The Internet socket address structure is named **sockaddr_in** and is defined by including `<netinet/in.h>` header.*

```
struct in_addr {
    in_addr_t    s_addr          /* 32-bit IP address */
};                               /* network byte ordered */

struct sockaddr_in {
    uint8_t      sin_len;        /* length of structure (16) */
    sa_family_t  sin_family;     /* AF_INET */
    in_port_t    sin_port;       /* 16-bit TCP or UDP port number */
                                   /* network byte ordered */
    struct in_addr sin_addr;     /* 32-bit IPv4 address */
                                   /* network byte ordered */
    char         sin_zero[8];    /* unused */
};
```

Figure 2.18

System Calls for Elementary TCP Sockets

```
#include <sys/types.h>
```

```
#include <sys/socket.h>
```

socket Function

```
int socket ( int family, int type, int protocol );
```

family: specifies the protocol family {AF_INET for TCP/IP}

type: indicates communications semantics

SOCK_STREAM stream socket TCP

SOCK_DGRAM datagram socket UDP

SOCK_RAW raw socket

protocol: set to 0 except for raw sockets

returns **on success**: **socket descriptor** {a small nonnegative integer}

on error: -1

Example:

```
if (( sd = socket (AF_INET, SOCK_STREAM, 0)) < 0)  
    err_sys (“socket call error”);
```

connect Function

```
int connect (int sockfd, const struct sockaddr *servaddr, socklen_t addrlen);
```

sockfd: a socket descriptor returned by the socket function

**servaddr*: a pointer to a socket address structure

addrlen: the size of the socket address structure

The socket address structure must contain the *IP address* and the *port number* for the connection wanted.

In TCP **connect** initiates a three-way handshake. **connect** returns only when the connection is established or when an error occurs.

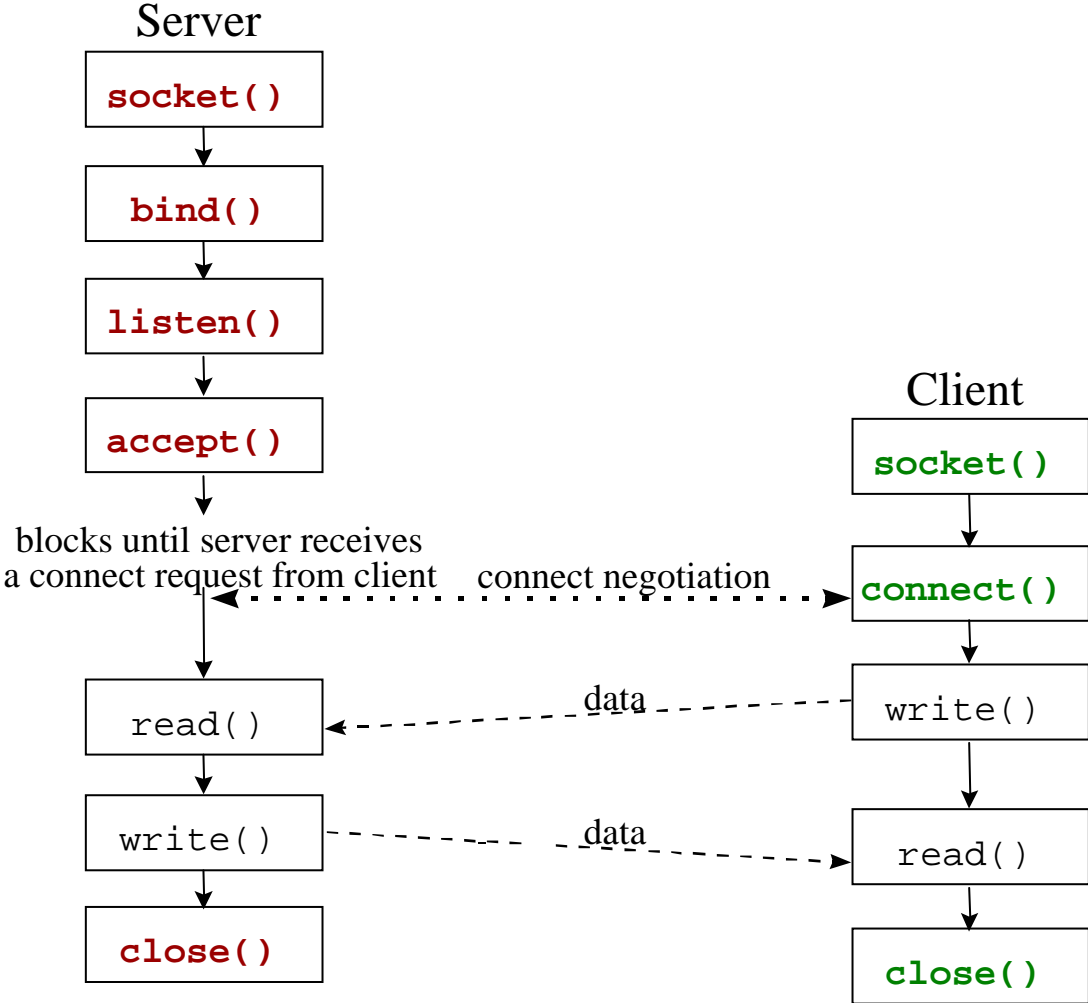

returns on success: 0

on error: -1

Example:

```
if ( connect (sd, (struct sockaddr *) &servaddr, sizeof (servaddr)) != 0)  
    err_sys(“connect call error”);
```

TCP socket calls

bind Function

```
int bind (int sockfd, const struct sockaddr *myaddr, socklen_t addrlen);
```

bind assigns a local protocol address to a socket.

protocol address: a 32 bit IPv4 address and a 16 bit TCP or UDP port number.

sockfd: a socket descriptor returned by the socket function.

**myaddr*: a pointer to a protocol-specific address.

addrlen: the size of the socket address structure.

Servers **bind** their “well-known port” when they start.

returns on success: 0

on error: -1

Example:

```
if (bind (sd, (struct sockaddr *) &servaddr, sizeof (servaddr)) != 0)  
    errsys (“bind call error”);
```

listen Function

```
int listen (int sockfd, int backlog);
```

listen is called **only** by a TCP server and performs two actions:

1. Converts an unconnected socket (*sockfd*) into a passive socket.
2. Specifies the maximum number of connections (*backlog*) that the kernel should queue for this socket.

listen is normally called before the **accept** function.

returns on success: 0
on error: -1

Example:

```
if (listen (sd, 2) != 0)  
    errsys (“listen call error”);
```

accept Function

```
int accept (int sockfd, struct sockaddr *cliaddr, socklen_t *addrlen);
```

accept is called by the TCP server to return the next completed connection from the front of the completed connection queue.

sockfd: This is the same socket descriptor as in **listen** call.

**cliaddr*: used to return the protocol address of the connected peer process (i.e., the client process).

**addrlen*: { this is a value-result argument }

before the accept call: We set the integer value pointed to by **addrlen* to the size of the socket address structure pointed to by **cliaddr*;

on return from the accept call: This integer value contains the actual number of bytes stored in the socket address structure.

returns on success: a new socket descriptor

on error: -1

accept Function

(cont.)

```
int accept (int sockfd, struct sockaddr *cliaddr, socklen_t addrlen);
```

For **accept** the first argument *sockfd* is the listening socket and the returned value is the connected socket.

The server will have one connected socket for each client connection accepted.

When the server is finished with a client, the connected socket must be closed.

Example:

```
sfd = accept (sd, NULL, NULL);  
if (sfd == -1) err_sys (“accept error”);
```

close Function

```
int close (int sockfd);
```

close marks the socket as closed and returns to the process immediately.

sockfd: This socket descriptor is no longer useable.

Note – TCP will try to send any data already queued to the other end before the normal connection termination sequence.

Returns **on success:** 0

on error: -1

Example:

```
close (sd);
```
