## Transmission Errors

## Error Detection and Correction

## Transmission Errors

- Transmission errors are caused by:
- thermal noise \{Shannon\}
- impulse noise (e..g, arcing relays)
- signal distortion during transmission (attenuation)
- crosstalk
- voice amplitude signal compression (companding)
- quantization noise (PCM)
- jitter (variations in signal timings)
- receiver and transmitter out of synch.

## Error Detection and Correction

- error detection :: adding enough "extra" bits to deduce that there is an error but not enough bits to correct the error.
- If only error detection is employed in a network transmission $\rightarrow$ retransmission is necessary to recover the frame (data link layer) or the packet (network layer).
- At the data link layer, this is referred to as ARQ (Automatic Repeat reQuest).

## Error Detection and Correction

- error correction : : requires enough additional (redundant) bits to deduce what the correct bits must have been.

Examples
Hamming Codes
FEC = Forward Error Correction found in MPEG-4 for streaming multimedia.

## Hamming Codes

codeword :: a legal dataword consisting of $m$ data bits and r redundant bits.

Error detection involves determining if the received message matches one of the legal codewords.
Hamming distance : : the number of bit positions in which two bit patterns differ.
Starting with a complete list of legal codewords, we need to find the two codewords whose Hamming distance is the smallest. This determines the Hamming distance of the code.

## Error Correcting Codes

| Char. | ASCII | Check bits |  |
| :---: | :---: | :---: | :---: |
| H a | 1100001 | 10111001001 |  |
| m | 1101101 | 11101010101 |  |
| m | 1101101 | 11101010101 | Note |
| i | 1101001 | 01101011001 |  |
| n | 1101110 | 01101010110 | Check bits occupy |
| g | 1100111 | 01111001111 | power of 2 slots |
|  | 0100000 | 10011000000 |  |
| c | 1100011 | 11111000011 |  |
| - | 1101111 | 10101011111 |  |
| d | 1100100 | 11111001100 |  |
| e | 1100101 | 00111000101 |  |
| Order of bit transmission |  |  |  |

Figure 3-7. Use of a Hamming code to correct burst errors.
(a) A code with poor distance properties

x = codewords $\quad \mathrm{o}=$ non-codewords

## Hamming Codes

- To detect $d$ single bit errors, you need a $d+1$ code distance.
- To correct $d$ single bit errors, you need a $2 d+1$ code distance.
$\rightarrow$ In general, the price for redundant bits is too expensive to do error correction for network messages.
$\rightarrow$ Network protocols use error detection and ARQ.

## Error Detection

Remember - errors in network transmissions are bursty.
$\rightarrow$ The percentage of damage due to errors is lower.
$\rightarrow$ It is harder to detect and correct network errors.

- Linear codes
- Single parity check code :: take $k$ information bits and appends a single check bit to form a codeword.
- Two-dimensional parity checks
- IP Checksum
- Polynomial Codes

Example: CRC (Cyclic Redundancy Checking)

## General Error Detection System

## Error Detection System Using Check Bits

## Two-dimensional Parity Check Code

| 1 | 0 | 0 | 1 | 0 | 0 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 0 | 1 | 0 | 0 | 0 | 1 |
| 1 | 0 | 0 | 1 | 0 | 0 |
| 1 | 1 | 0 | 1 | 1 | 0 |
| 1 | 0 | 0 | 1 | 1 | 1 |

Last column consists of check bits for each row

Bottom row consists of check bit for each column

| 1 | 0 | 0 | 1 | 0 | 0 |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 0 | 0 | 0 | 0 | 0 | 1 | $\longleftarrow$ |  |
| 1 | 0 | 0 | 1 | 0 | 0 |  |  |
| 1 | 1 | One |  |  |  |  |  |
| 1 | 1 | 0 | 1 | 1 | 0 |  |  |
| 1 | 0 | 0 | 1 | 1 | 1 |  |  |
|  | $\uparrow$ |  |  |  |  |  |  |

$$
\begin{array}{llllllll}
1 & 0 & 0 & 1 & 0 & 0 & & \\
0 & 0 & 0 & 0 & 0 & 1 & \longleftarrow \\
1 & 0 & 0 & 1 & 0 & 0 & & \text { Two } \\
1 & 0 & 0 & 1 & 1 & 0 & \longleftarrow \\
1 & 0 & 0 & 1 & 1 & 1
\end{array}
$$

Arrows indicate failed check bits

## Internet Checksum

```
unsigned short cksum(unsigned short *addr, int count)
            /*Compute Internet Checksum for "count" bytes
            * beginning at location "addr".
            */
    register long sum = 0;
    while ( count > 1 ) {
        /* This is the inner loop*/
            sum += *addr++;
            count -=2;
        }
        /* Add left-over byte, if any */
    if ( count > 0 )
        sum += *addr;
        /* Fold 32-bit sum to 16 bits */
    while (sum >>16)
        sum = (sum & 0xffff) + (sum >> 16) ;
    return ~sum;
}
```

Networks: Transmission Errors

## Polynomial Codes [LG\&W pp. 161-167]

- Used extensively.
- Implemented using shift-register circuits for speed advantages.
- Also called CRC (cyclic redundancy checking) because these codes generate check bits.
- Polynomial codes : : bit strings are treated as representations of polynomials with ONLY binary coefficients (0's and 1's).

## Polynomial Codes

- The $k$ bits of a message are regarded as the coefficient list for an information polynomial of degree $k-1$.

Example: 1011000

$$
i(x)=x^{6}+x^{4}+x^{3}
$$

## Polynomial Notation

- Encoding process takes $i(x)$ produces a codeword polynomial $b(x)$ that contains information bits and additional check bits that satisfy a pattern.
- Let the codeword have $n$ bits with $k$ information bits and $n-k$ check bits.
- We need a generator polynomial of degree $n-k$ of the form

$$
G=g(x)=x^{n-k}+g_{n-k-1} x^{n-k-1}+\ldots+g_{1} x+1
$$

Note - the first and last coefficient are always 1.

## CRC Codeword

## Polynomial Arithmetic

Addition:

$$
\begin{aligned}
\left(x^{7}+x^{6}+1\right)+\left(x^{6}+x^{5}\right) & =x^{7}+(1+1) x^{6}+x^{5}+1 \\
& =x^{7}+x^{5}+1
\end{aligned}
$$

Multiplication: $\quad(x+1)\left(x^{2}+x+1\right)=x^{3}+x^{2}+x+x^{2}+x+1=x^{3}+1$

$$
x^{3}+x^{2}+x=q(x) \text { quotient }
$$

Division:
divisor

$$
35 \begin{array}{r}
\frac{3}{122} \\
\frac{105}{17}
\end{array}
$$

## CRC Algorithm

## CRC Steps:

1) Multiply $i(x)$ by $x^{n-k}$ (puts zeros in ( $n-k$ ) low order positions)
2) Divide $x^{n-k} i(x)$ by $g(x)$

3) Add remainder $r(x)$ to $x^{n-k} i(x)$
(puts check bits in the $n$ - $k$ low order positions):

$$
b(x)=x^{n-k i}(x)+r(x) \quad \text { transmitted codeword }
$$

Information: $(1,1,0,0) \Longrightarrow i(x)=x^{3}+x^{2}$
Generator polynomial: $g(x)=x^{3}+x+1$
Encoding: $\quad x^{3} i(x)=x^{6}+x^{5}$
$x^{3}+x^{2}+x$
$\left.x^{3}+x+1\right) x^{6}+x^{5}$
$x^{6}+x^{4}+x^{3}$
$x^{5}+x^{4}+x^{3}$
$x^{5}+\quad x^{3}+x^{2}$
$x^{4}+\quad x^{2}$
$x^{4}+x^{2}+x$
1011) 1100000
1011
1110
1011
1010
1011
Transmitted codeword:

$$
\begin{aligned}
& b(x)=x^{6}+x^{5}+x \\
\Rightarrow & \underline{b}=(1,1,0,0,0,1,0)
\end{aligned}
$$

|  |  |  |  |  |  |  |  |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 1001 | 1 | 0 | 0 | 0 | 0 | 1 | 0 | 1 | 0 |  |  |  |
| 1 | 1 | 0 | 1 | 0 | 1 | 1 | 0 | 1 | 1 | 0 | 0 | 0 | 0

## Generator Polynomial Properties for Detecting Errors

GOAL :: minimize the occurrence of an error going undetected.
Undetected means
$E(x) / G(x)$ has no remainder.

# Generator Polynomial Properties for Detecting Errors 

1. Single bit errors:

$$
e(x)=x^{i}
$$

$$
0 \leq i \leq n-1
$$

If $g(x)$ has more than one term, it cannot divide $e(x)$
2. Double bit errors: $\quad e(x)=x^{i}+x^{j} \quad 0 \leq i<j \leq n-1$

$$
=x^{i}\left(1+x^{j-i}\right)
$$

If $g(x)$ is primitive polynomial, it will not divide $\left(1+x^{j-i}\right)$ for $j-i \leq 2^{n-k}-1$
3. Odd number of bit errors: $e(1)=1$ If number of errors is odd.
If $g(x)$ has $(x+1)$ as a factor, then $g(1)=0$ and all codewords have an even number of 1 s .

## Generator Polynomial Properties

 for Detecting Errors
$e(x)=x^{i} d(x) \quad$ where $\operatorname{deg}(d(x))=\mathrm{L}-1$
$g(x)$ has degree $n-k$;
$g(x)$ cannot divide $d(x)$ if $\operatorname{deg}(g(x))>\operatorname{deg}(d(x))$

- If $\mathrm{L}=(\mathrm{n}-\mathrm{k})$ or less: all errors will be detected
- If $\mathbf{L}=(\mathbf{n}-\mathbf{k}+\mathbf{1}): \quad \operatorname{deg}(d(x))=\operatorname{deg}(g(x))$
i.e. $d(x)=g(x)$ is the only undetectable error pattern, fraction of bursts which are undetectable $=\mathbf{1} / \mathbf{2}^{L-2}$
- If $\mathrm{L}>(\mathrm{n}-\mathrm{k}+1)$ : fraction of bursts which are undetectable $=\mathbf{1} / \mathbf{2}^{n-k}$

## Standard Generating Polynomials

- CRC-16 $=\mathrm{X}^{16}+\mathrm{X}^{15}+\mathrm{X}^{2}+1$
- CRC-CCITT $=\mathrm{X}^{16}+\mathrm{X}^{12}+\mathrm{X}^{5}+1$
- CRC-32 $=\mathrm{X}^{32}+\mathrm{X}^{26}+\mathrm{X}^{23}+\mathrm{X}^{22}$
$+\mathrm{X}^{16}+\mathrm{X}^{12}+\mathrm{X}^{11}+\mathrm{X}^{10}$
$+X^{8}+X^{7}+X^{5}+X^{4}$
$+X^{2}+X+1$
