## Circuit Switching

- Seeking out and establishing a physical copper path end-to-end [historic definition] .
- Circuit switching implies the need to first set up a dedicated, end-to-end path for the connection before the information transfer takes place.
- Once the connection is made the only delay is propagation time.

## Circuit Switching

## Store-and-Forward Networks

- Intermediate processors (IMPS, nodes, routers, gateways, switches) along the path store the incoming block of data.
- Each block is received in its entirety, inspected for errors, and retransmitted along the path to the destination. This implies buffering at the router and one transmission time per hop.

## Message Switching

- A store-and-forward network where the block of transfer is a complete message.
- Since messages can be quite large, this can cause:
- buffering problems
- high mean delay

## Packet Switching

- A store-and-forward network where the block of transfer is a complete packet. A packet is a variable length block of data with a tight upper bound.
$\Rightarrow$ Using packets improves mean message delay.

## Cell Switching

## 53 bytes

- A network where the unit of transfer is a small, fixed size block of date (i.e., one cell).
- ATM (Asynchronous Transfer Mode) networks use 53 byte cells.

## Packet Switched Networks

## Connection-oriented Protocols

- A setup stage is used to determine the end-toend path before a connection is established.
- Data flow streams are identified by some type of connection indicator (e.g. OSI, X.25, SNA).

## Connection-Oriented

## Concatenation of Virtual Circuits

Figure 5-45.Internetworking using concatenated virtual circuits.

## Packet Switched Networks

## Connectionless Protocols

- No set up is needed.
- Each packet contains information which allows the packet to be individually routed hop-by-hop through the network.

## Connectionless Internetworking

Figure 5-46. A connectionless internet.

## Datagram vs Virtual Circuit

Datagram

- Each datagram packet may be individually routed.
Virtual Circuit
- Virtual circuit set up is required.
- All packets in a virtual circuit follow the same path.

by the network. Packets are labeled with a destination address and may arrive at the destination node out of sequence.
