# Distributed Denial of Service (DDoS)

Defending against Flooding-Based DDoS Attacks: A Tutorial Rocky K. C. Chang

> Presented by Adwait Belsare (<u>adwait@wpi.edu</u>) Suvesh Pratapa (<u>suveshp@wpi.edu</u>)

Modified Slightly by Bob Kinicki 13 October 2009

Introduction

- The DDoS Problems
- Solutions to the DDoS Problems
- An Internet Firewall?
- A Comparison of Four detect and Filter Approaches
- Conclusions of the tutorial

#### **Introduction**

A typical DDoS attack consists of amassing a large number of compromised hosts to send useless packets to jam a victim or its Internet connection or both.

Can be done in following ways:

- To exploit system design weaknesses such as ping to death .
- Impose computationally intensive tasks on the victim such as encryption and decryption
- Flooding based DDoS Attack.

#### **DDoS** Attacks

Do not rely on particular network protocols or system design weaknesses

Consist of sufficient number of compromised hosts amassed to send useless packets toward a victim around the same time.

Have become a major threat due to availability of a number of user-friendly attack tools on one hand and lack of effective solutions to defend against them on the other.

## Attacks Reported

May/June, 1998 First primitive DDoS tools developed in the underground - Small networks, only mildly worse than coordinated point-to-point DoS attacks. August 17, 1999 Attack on the University of Minnesota reported to UW network operations and security teams. February 2000 Attack on Yahoo, eBay, Amazon.com and other popular websites. A recent study observed more than 12,000 attacks during a three week period.

Reference: http://staff.washington.edu/dittrich/misc/ddos/timeline.html

#### The DDoS Problems

## The attacks can be classified into: Direct Attacks. Reflector Attacks.

#### **Direct Attacks**

Consists of sending a large number of attack packets directly towards a victim.

Source addresses are usually spoofed so the response goes elsewhere.

#### Examples:

- TCP-SYN Flooding: The last message of TCP's 3 way handshake never arrives from source.
- Congesting a victim's incoming link using ICMP messages, RST packets or UDP packets.
- Attacks use TCP packets (94%), UDP packets (2%) and ICMP packets(2%).

Agent Programs: Trinoo, Tribe Flood Network 2000, and Stacheldraht

#### **Reflector Attacks**

Uses innocent intermediary nodes (routers and servers) known as reflectors.

- An attacker sends packets that require responses to the reflectors with the packets' inscribed source address set to victim's address.
- Can be done using TCP, UDP, ICMP as well as RST packets.

#### Examples:

- Smurf Attacks: Attacker sends ICMP echo request to a subnet directed broadcast address with the victim's address as the source address.
- SYN-ACK flooding: Reflectors respond with SYN-ACK packets to victim's address.

## **Reflector Attack**

- Cannot be observed by backscatter analysis, because victims do not send back any packets.
- Packets cannot be filtered as they are legitimate packets.

#### **DDoS Attack Architectures**

**Figure 2.** DDoS attack architectures for a) direct and b) reflector attacks.

## Some Reflector Attack Methods

	Packets sent by an attacker to a reflector (with a victim's address as the source address)			
Smurf	ICMP echo queries to a subnet-directed broadcast address			
SYN flooding	TCP SYN packets to public TCP servers (e.g., Web servers)			
RST flooding	TCP packets to nonlistening TCP ports			
ICMP flooding	<ul> <li>ICMP queries (usually echo queries)</li> <li>UDP packets to nonlistening UDP ports</li> <li>IP packets with low TTL values</li> </ul>			
DNS reply flooding	DNS (recursive) queries to DNS servers			
	Packets sent by the reflector to the victim in response			
Smurf	Packets sent by the reflector to the victim in response ICMP echo replies			
Smurf SYN flooding	Packets sent by the reflector to the victim in response ICMP echo replies TCP SYN-ACK packets			
Smurf SYN flooding RST flooding	Packets sent by the reflector to the victim in response ICMP echo replies TCP SYN-ACK packets TCP RST packets			
Smurf SYN flooding RST flooding ICMP flooding	Packets sent by the reflector to the victim in response ICMP echo replies TCP SYN-ACK packets TCP RST packets • ICMP replies (usually echo replies) • ICMP port unreachable messages • ICMP time exceeded messages			

#### How many attack packets are needed?

If a victim has resources to admit N half open connections, its capacity of processing incoming SYN packets can be modeled as a G/D/INFINITY/N queue where :

G = General arrival process for the SYN packets. D = Deterministic lifetime of each half-open connection if not receiving the third handshaking message.

## <u>Minimal rates of SYN packets to stall TCP</u> servers in SYN flooding attacks

attacks.

WIN system offers better protection against SYN flooding based on maximum lifetimes of half-open connections.

1Mb/s connection is sufficient to stall all three servers with N<= 10,000<sup>1.4</sup>

#### Solutions to the DDoS Problems

- There are three lines of defense against the attack:
  - Attack Prevention and Preemption (before the attack)
  - Attack Detection and Filtering (during the attack)
  - Attack Source Traceback and Identification (during and after the attack)

A comprehensive solution should include all three lines of defense.

#### Attack Prevention and Preemption

- On the passive side, protect hosts from master and agent implants by using signatures and scanning procedures to detect them.
- Monitor network traffic for known attack messages sent between attackers and masters.
- On the active side, employ cyber-informants and cyber-spies to intercept attack plans (e.g., a group of cooperating agents).
- This line of defense alone is inadequate.

### Attack Source Traceback and Identification

An after-the-fact response.

IP Traceback: Identifying actual source of packet without relying on source information.

- Routers can record information they have seen.
- Routers can send additional information about seen packets to their destinations.
- Infeasible to use IP Traceback. Why?
  - Cannot always trace packets' origins. (NATs and Firewalls!)
  - IP Traceback also ineffective in reflector attacks.

Nevertheless, it is at least a good idea and is helpful for post-attack law enforcement.

#### Two phases:

- DDoS Attack Detection: Identifying DDoS attack packets.
- Attack Packet Filtering: Classifying those packets and dropping them.

(Overall performance depends on effectiveness of both phases.)

#### Effectiveness of Detection

- FPR (False Positive Ratio): No. of *false positives*/Total number of confirmed normal packets
- FNR (False Negative Ratio):
   No. of *false negatives*/Total number of confirmed attack packets

Both metrics should be low!

#### Effectiveness of Filtering

- \*Effective attack detection ≠ Effective packet filtering
   Detection phase uses victim identities (Address or Port No.), so even normal packets with same signatures can be dropped.
- NPSR (Normal Packet Survival Ratio):

Percentage of normal packets that can *survive* in the midst of an attack

NPSR should be high!

#### At Source Networks:

- Can filter packets based on address spoofing.
- Direct attacks can be traced easily, difficult for reflector attacks.
- Need to ensure all ISPs have ingress packet filtering. Very difficult (Impossible?)

#### At the Victim's Network:

- DDoS victim can detect attack based on volume of incoming traffic or degraded performance. Commercial solutions available.
- Other mechanisms: *IP Hopping* (Host frequently changes it's IP address when attack is detected. DNS tracing can still help the attackers)
- Last Straw: If incoming link is jammed, victim has to shut down and ask the upstream ISP to filter the packets.

#### At a Victim's Upstream ISP Network:

- Victim requests frequently to filter packets.
- Can be automated by designing intrusion alert systems, which should be designed carefully.
- Not a good idea though. Normal packets can still be dropped, and this upstream ISP network can still be jammed under largescale attacks.

#### At further Upstream ISP Networks:

- The above approach can be further extended to other upstream networks.
- Effective only if ISP networks are willing to co-operate and install packet filters.

## An Internet Firewall

 A bipolar defense scheme cannot achieve both effective packet detection and packet filtering.
 Hence a proposal to deploy a global defense infrastructure.

The plan is to detect attacks right at the Internet core!

- Two methods, which employ a set of distributed nodes in the Internet to perform attack detection and packet filtering.
  - Route-based Packet Filtering Approach (RPF)
  - Distributed Attack Detection Approach (DAD)

## Route-Based Packet Filtering (RPF)

Extends the ingress packet filtering approach to the Internet.

- Distributed packet filters examine the packets based on addresses and BGP routing information.
- A packet is considered an attack packet if it comes from an unexpected link.
- Major Drawbacks
  - Requiring BGP messages to carry the needed source addresses
    - Overhead!
  - Deployment is still tough! Filters need to be placed in almost 1800 AS (when there were 10,000 Ass) and the no. of AS is continuously increasing.
  - Cannot filter reflected packets.

### **Distributed Attack Detection (DAD)**

- Deploys a set of distributed Detection Systems (DSs) to observe network anomalies and misuses.
- Anomaly detection: Observing and detecting traffic patterns that significantly deviate from normal (e.g., unusual traffic intensity for specific packet types.
- Misuse detection: Identifying traffic that matches a known attack signature.
- DSs rely mainly on anomaly detection. Various DSs exchange attack information from local observations. This is stateful in respect to the DDoS attacks.
- Designing an effective and deployable architecture for the DAD approach is a challenging task.

## **Distributed Attack Detection**

#### **DS Design Considerations**

#### Other considerations:

- Filters should be installed only on attack interfaces on 'CONFIRMED' state
- All DSs should be connected 'always'
- Works in Progress:
  - Intrusion Detection Exchange Protocol Intrusion Detection Message Exchange Format

Figure 5. a) High-level DS architecture and b) a state diagram of two-level attack detection in the distributed detection approach.

## **Distributed Attack Detection**

#### **Quickest Detection Problem Formulation**

Let *i*th Sample of instantaneous traffic intensity be A<sub>i</sub>

Figure 6. Relevant events in DDoS attack detection.

## Limitations and Open Problems

Limitations of Mathematical Nature: Choices of global / local thresholds, traffic modeling, etc.

#### Performance Aspects:

- Two-level detection not useful for DDoS attacks of short durations.
- Flash crowds can trigger false alarms. Algorithm should adapt to this new 'normality'
- Other attack patterns:
  - DeS attacks that use 'pulsing agents' with short bursts.
  - Using different sets of attack agents each time.

#### **Comparison of Four Detect-And-Filter Approaches**

	Ubiquitous ingress packet filtering (UIPF)	Route-based packet filtering (RPF)	Local attack detection (LAD)	Distributed attack detection (DAD)
1. Detection locations	All ISP networks that are connected to leaf networks in the Internet	A set of packet filters distributed in the Internet	Potential victims' networks and/or their upstream ISP networks	A set of detection systems distributed in the Internet
2. Filtering locations	Same as the detection locations	Same as the detection locations	Same as the detection locations and further upstream ISP networks if backpressure is used	Same as the detection locations and other upstream networks
3. Attack signatures	Spoofed source IP addresses	Spoofed source IP addresses according to the BGP routing information	Traffic anomalies and misuses detected by local intrusion detection systems	Mainly traffic anomalies observed from the set of distributed detection systems
4. False positive ratio (FPR)	= 0	= 0 if the BGP routes are correct	≥ 0 (= 1 in a sufficiently large-scale DDoS attack)	≥ 0 (high if the detection algorithms are overly sensitive)
5. False negative ratio (FNR)	≥ 0 (= 0 if all attack packets use spoofed addresses)	≥ 0 (small if most attack packets use spoofed addresses)	≥ 0 (= 0 in a sufficiently large-scale DDoS attack)	≥ 0 (high if the detection algorithms are not sensitive enough)
6. Normal packet survival ratio (NPSR)	≥ 0 (= 1 if all attack packets use spoofed addresses)	≥ 0 (large if most attack packets use spoofed addresses and the number of the AS nodes involved in the packet filtering is sufficiently large)	≥ 0 (= 0 in a sufficiently large-scale DDoS attack)	≥ 0 (high if both the false negative and positive ratios are low, and the set of detection systems are placed optimally in the Internet)
7. New communication protocols	Not required	Modifications to BGP protocols	Attack alert protocols between victims and their upstream ISP networks if backpressure is used	Protocols between detection systems
8. Computation requirement	Low	Moderate	Low	High
9. Deployment difficulty	Very high	High	Moderate without backpressure mechanisms	High
10. Technical complexity	Low	High	Moderate without backpressure mechanisms	High

Table 2. A comparison of four approaches to detecting and filtering DDoS attack packets.

## Conclusion from this tutorial

- Current defense mechanisms are far from adequate.
- One promising direction is to develop a global infrastructure, an Internet Firewall.
- Deployment and design considerations should be worked upon.

We see that DDoS Defense is possible through careful planning, and this tutorial covered defense mechanisms which try to discover and slow down bad clients.

## Thank You!
