

TCP Sliding Windows, with Flow Control, and Congestion Control

Based on
Peterson and Davie Textbook

Sliding Windows

- Normally a data link layer concept
- Interest is understanding TCP mechanism at the transport layer.
- Each frame is assigned a sequence number - **SeqNum**
- The sender maintains three variables: send window size (**SWS**), last ACK received (**LAR**), and last Frame sent (**LFS**)

Sender variables

- **SWS** :: the upper bound on the number outstanding frames (not ACKed) the sender can transmit
- **LAR** :: the sequence number of the last ACK received
- **LFS** :: the sequence number of the last frame sent

Sender Invariant

$$\text{LFS} - \text{LAR} \leq \text{SWS}$$

Sender Window

- An arriving ACK → **LAR** moves right 1
→ sender can send one more frame
- Associate a *timer* with each frame sender transmits
- Sender retransmits the frame if the timer *times out*
- Sender buffer :: up to **SWS** frames

Receiver variables

- **Receiver window size (RWS)** :: the upper bound on the number of out-of-order frames the receiver is willing to accept
- **Largest acceptable frame (LAF)** :: the sequence number of the largest acceptable frame
- **Last frame received (LFR)** :: the sequence number of the last frame received

Receiver Invariant

$$LAF - LFR \leq RWS$$

Receiver Window

- When a frame arrives with **SeqNum**
 - If (**SeqNum** \leq **LFR** or **SeqNum** $>$ **LAF**)
*the frame is **discarded** because it is outside the window.*
 - If (**LFR** $<$ **SeqNum** \leq **LAF**)
*the frame is **accepted**.*

Receiver ACK Decisions

SeqNumToAck :: largest sequence number **not yet ACKed** such that all frames \leq **SeqNumToAck** have been received.

- Receiver ACKs receipt of **SeqNumToAck** set

$$\text{LFR} = \text{SeqNumToAck}$$

$$\text{LAF} = \text{LFR} + \text{RWS}$$

TCP Sliding Windows

- * *switch from packet pointers to byte pointers*
- Guarantees reliable delivery of data.
- Ensures data delivered in order.
- Enforces flow control between sender and receiver.
- The idea is: the sender does not overrun the receiver's buffer

Receiver's Advertised Window

- The big difference is the size of the sliding window size at the receiver is not fixed.
- The receiver *advertises* an adjustable window size (**AdvertisedWindow** field in TCP header).
- Sender is limited to having no more than **AdvertisedWindow** bytes of unACKed data at any time.

TCP Flow Control

- The discussion is similar to the previous sliding window mechanism except we add the complexity of sending and receiving *application processes* that are filling and emptying their local buffers.
- Also introduce complexity that buffers are of finite size, but not worried about where the buffers are stored.

MaxSendBuffer

MaxRcvBuffer

TCP Flow Control

- Receiver throttles sender by advertising a window size no larger than the amount it can buffer.

On TCP receiver side:

$\text{LastByteRcvd} - \text{LastByteRead} \leq \text{MaxRcvBuffer}$

to avoid buffer overflow!

TCP Flow Control

TCP receiver advertises:

$$\text{AdvertisedWindow} = \text{MaxRcvBuffer} - (\text{LastByteRcvd} - \text{LastByteRead})$$

i.e., the amount of free space available in the receive buffer.

TCP Flow Control

TCP sender must adhere to **AdvertisedWindow** from the receiver such that

$\text{LastByteSent} - \text{LastByteAcked} \leq \text{AdvertisedWindow}$

or use **EffectiveWindow**:

$\text{EffectiveWindow} = \text{AdvertisedWindow} - (\text{LastByteSent} - \text{LastByteAcked})$

TCP Flow Control

Sender Flow Control Rules:

1. $\text{EffectiveWindow} > 0$ for sender to send more data

2. $\text{LastByteWritten} - \text{LastByteAked} \leq \text{MaxSendBuffer}$

equality \rightarrow *send buffer is full!!*

\rightarrow *TCP sender must **block** sender application.*

TCP Congestion Control

- **CongestionWindow** :: a variable held by source for each connection.
- * TCP is modified such that the maximum number of bytes of unacknowledged data allowed is the *minimum of* **CongestionWindow** and **AdvertisedWindow**.

MaxWindow :: $\min(\text{CongestionWindow}, \text{AdvertisedWindow})$

TCP Congestion Control

And finally, we have:

$$\text{EffectiveWindow} = \text{MaxWindow} - (\text{LastByteSent} - \text{LastByteAked})$$

The idea :: the source effective window can be **no faster** than the slowest of the network (*routers*) or the destination Host.

* *The TCP source receives implicit and/or explicit indications of congestion by which to reduce the size of Congestion Window.*
